ABSTRACT

Flurbiprofen is a potent non-steroidal anti-inflammatory drug that can be used for rheumatoid arthritis, osteoarthritis, alkylosing spondylitis, tendinitis etc. Its shorter biological half life (3 – 4.5 hrs) necessitates it to be administered in frequent doses of 50 – 100mg two to four times a day. The main objective of this study was to develop suitable microparticulate system of Flurbiprofen for controlled release delivery system by varying the sodium alginate, PEG 6000 and HPMC concentrations. In the present work Flubriprofen microbeads were formulated using sodium alginate by ionotropic gelation technique. Prepared beads were evaluated for granulometric studies, micromeretic, scanning electron microscopy, drug entrapment efficiency and in-vitro dissolution studies etc. The prepared beads were free flowing and white in colour. The drug loaded beads showed 87.5– 98.8 % drug entrapment, which was found to increase with increase in sodium alginate, HPMC, PEG 6000 concentration. Scanning electron microscopy revealed that the beads were almost spherical and rough in structure. The flow property of the all the batches of prepared microbeads were estimated by angle of repose and found to be in the range of $24^0 50' - 33^0 20'$ *In vitro* drug release study of these microbeads indicated controlled release of Flurbiprofen, formulations showed a release of 73.67-93.5% at the end of 10 h. Hence from the observation of all results of the different batches fourth and fifth showed controlled release action and improved drug availability. The release of Flurbiprofen was found to be affected by concentration of polymers such as sodium alginate, PEG 6000 and HPMC By the observation of accelerated stability studies fourth and fifth batch formulations were found to be the best formulations. From this study, it could be concluded that the spherical and free flowing microbeads of Flurbiprofen could be successfully prepared by ionotropic gelation technique with high entrapment efficiency and controlled release characteristics**.**

INTRODUCTION

Flurbiprofen [1,1'-biphenyl]-4-acetic acid, 2-fluoro-alpha-methyl-, is an important analgesic and non-steroidal anti inflammatory drug (NSAID) also with anti-pyretic properties whose mechanism of action is inhibition ofprostaglandin synthesis. It is used in the therapy of rheumatoid disorders. Flurbiprofen is rapidly eliminated from theblood and its plasma elimination half-life is 3-6 hours. In order to maintain therapeutic plasma levels the drug mustbe administered approximately 150-200mg daily by oral in divided doses[1].To overcome inherent drawbacks associated with conventional dosage forms of Flurbiprofen, an attempt is beingmade to develop an alternative drug delivery system in the form of micrbeads for controlled release. NSAIDS are the cyclooxygenases enzyme inhibitors, which results in the direct inhibition of the biosynthesis of prostaglandins and thromboxane's from arachidonic acid. NSAIDS are used for the relief of mild to moderate pain, minor febrile conditions and for acute and

chronic inflammatory disorders such as osteoarthritis, rheumatoid arthritis and ankylosing spondylitis. Prostaglandins, prostacyclin (PGI_2) and thromboxane A_2 (TXA_2) are produced from arachidonic acid by enzyme cyclooxygenase which exists in a consecutive (COX-1) and an inducible (COX-2) isoforms, the former serves physiological housekeeping functions while the latter, normally present in minute quantities, is induced by cytokines and other signal molecules at the site of inflammation[2].The objective of controlled release drug delivery includes two important aspects namely spatial placement and temporal delivery of drug. Spatial placement relates to targeting a drug to a specific organ or tissue, while temporal delivery refers to controlling the rate of drug delivery to the target tissue. The objective in designing a controlled release system is to deliver drug at a necessary to achieve and maintain a constant drug blood level. Sustained release systems include any drug delivery system that "achieves slow release of drug over an extended period of time". If the system only extends the duration of release without reproducible kinetics it is considered a prolonged release system[3, 4, 5].Micro-encapsulation is a process whereby small discrete solid particles or small liquid droplets are surrounded or enclosed, by an intact shell. It has been widely employed in the design of controlled release and sustained release dosage forms.Many drugs have been microencapsulated to reduce gastric and other gastrointestinal tract irritation. The local irritation and release properties of a number of topically applied products can be altered by microencapsulation. This process is also used to mask the taste of bitter drugs[6, 7, 8]. Microencapsulation method by Ionotropic Gelation technique involves the production of strong spherical beads with a narrow particle size distribution and low friability could be prepared with high yield and a drug content approaching 98%. The flow properties of micronized or needle like drug crystals were significantly improved by this agglomeration technique when compared with non-agglomerated drug crystals. It has been suggested that the cross-links were caused either by simple ionic bridging of two carboxyl groups on adjacent polymer chains via calcium ions or by chelating of single calcium ions by hydroxyl and carboxyl groups on each of a pair of polymer chains[9,10,11]. Microbeads were prepared by using sodium alginate as a polymer and calcium chloride as a cross-linking agent.

MATERIALS AND METHODS

Materials

Flurbiprofen was obtained as a gift sample from Sun Pharmaceuticals Ltd., Mumbai. Hydroxy Propyl Methyl Cellulose was obtained from Colorcol, U.K. Poly Ethylene Glycol-6000, Sodium Alginate, Calcium Chloride, Petroleum Ether was obtained from S.D. Fine Chem. Ltd., Mumbai.

Methods

1. Preformulation study

Prior to the development of the dosage forms the preformulation study was carried out. Hence infra-red spectra of the physical mixture of the drug and the polymers chosen were taken. Also the infra-red spectra of the drug[12] and polymers were run individually. The application of infra-red spectroscopy lies more in qualitative identification of substance either in pure form or in mixtures and as a tool in establishing the structure.

2. Standard plot for Flurbiprofen

Acid Buffer(P^H1.2): accurately weighed 10 mg of Flurbiprofen was dissolved in 10ml of methanol and made up to mark with P^H 1.2 in a 100ml volumetric flask to get working stock solution having concentration of 100µg/ml.

P^H 6.0: accurately weighed 10mg of Flurbiprofen was dissolved in 100ml of P^H 6.0 solution to get working stock solution having concentration of 100µg/ml Phosphate Buffer (P^H 7.2): the above procedure was followed but instead of P^H 6.0, phosphate buffer P^H 7.2 was used. From the above stock solution aliquots of 1.25ml, 2.5ml, 3.75ml, 5.0ml, 6.25ml and 7.5ml were pipetted out into a series of 25ml volumetric flasks and volume was made up to 25ml in order to get a concentration ranging from 5-30µg/ml. The absorbance of the resulting solution was then measured at 247nm using UV spectrophotometer against respective parent solvent as a blank. The standard curve was obtained by plotting absorbance V/S. concentration in µg/ml[13, 14]. Results are given in table 1 and figure 1.

3. Preparation of microbeads

Mircobeads were prepared by Ionotropic gelation technique. In this method weighed quantity of flurbiprofen was added to 50 ml sodium alginate solution and thoroughly mixed with a stirrer at 500 rpm. For the formation of microbeads, 50ml of this solution was extruded dropwise from a needle into 100 ml aqueous calcium chloride solution and stirred at 100 rpm. After stirring for 10 minutes the obtained microbeads were washed with water and dried

at 70^{0}C for 6 hrs in an oven.Three sets of microbeads were prepared. First set were prepared using only sodium alginate, second set were prepared in a combination of HPMC and sodium alginate, third set were prepared in combination of PEG-6000 and sodium alginate[15].Composition of microbeads is given in table 2.

EVALUATION PARAMETERS OF MICROBEADS

1. Granulometric study

As particle size has very significant effect on the release profile of microbeads, granulometric study was conducted to determine the particle size distribution pattern. For this study, sieve analysis was carried out on mechanical sieve shaker, using different meshes (#12, #16, #20, #30) of American society of testing materials (ASTM).

2. Flow property

Angle of repose method was employed to assess the flowability. Angle of repose is defined as the maximum angle possible between the surface of a pile of powder and the horizontal plane.

It was measured by fixed funnel method. The fixed funnel method employs a funnel that was secured with its tip at a given height H, above graph paper that was placed on a flat horizontal surface. Microbeads were carefully poured through the funnel until the apex of the conical pile just touched the tip of the funnel. The angle of repose was determined by using the equation

$$\text{Tan}\theta = H/R \quad \text{or} \quad \theta = \tan^{-1} H/R$$

Where θ = angle of repose,
R = radius of base of the pile
H = height of the pile

3. Drug Entrapment Efficiency

Drug entrapment efficiency of Flurbiprofen microbeads was performed by accurately weighing 50mg of microbeads and suspended in 100ml of simulated intestinal fluid of P^H 7.2±0.1 and it was kept for 24 hrs. Next day it was stirred for 15 mins, and subjected for filtration. After suitable dilution, Flurbiprofen content in the filtrate was analysed spectrophotometrically at 247nm using shimadzu 1201 UV-visible spectrophotometer.

4. In-vitro Dissolution Studies

In-vitro drug release profile of the microbeads was evaluated using rotating basket dissolution apparatus. 900ml of acid buffer(P^H 1.2), duodenal fluid (P^H 6.0) and phosphate buffer (P^H 7.2) maintained at 37±0.5^{0}C were used as dissolution media respectively, and the basket was rotated at a constant speed of 50 rpm. Accurately weighed amount of microbeads equivalent to 200 mg of drug were placed in the baskets.Aliquotes of samples were withdrawn after 2nd, 4th, 6th, 8th and 12th hr. fresh dissolution media was replaced to maintain the original volume. The samples withdrawn were filtered, diluted suitably and analysed at 247nm spectrophotometrically for drug release.

5. Scanning electron microscopy

The samples were dried thoroughly in vacuum desiccator before mounting on brass specimen studies. The samples were mounted on specimen studies using double sided adhesive tape, and gold-palladium alloy of 120 A^{0}kness was coated on the sample using sputter coating unit in an argon ambient of 8-10 pascal with plasma voltage about 2 KV and discharge current about 20 MA. The sputtering was done for nearly 3 minutes to obtain uniform coating on the samples to enable good quality SEM images. The SEM was operated at low accelerating voltage of about 15 KV with load current of about 80 MA.

6. Accelerated Stability Studies

The formulations were stored in oven at 37±1^{0}C and 60±1^{0}C for a period of six weeks. The samples were analysed for drug content every week by spectrophotometer at 247nm.[16, 17]

RESULTS AND DISCUSSION

1. Preformulation study

The characteristic absorption peaks of flurbiprofen were obtained at 1701 cm^{-1}, 1417 cm^{-1}, 1216 cm^{-1}. The IR spectra's of the drug and polymer combinations were compared with the spectra of pure drug and individual polymers. The principle peaks obtained for the combinations were almost similar to that of the drug. The IR spectra of drug-HPMC, drug-PEG 6000, drug- sodium alginate did not show many changes.

2. Granulometric study

In the granulometric study it is observed that about 67 to 79 percent of microbeads were of 16 mesh size, which proves the flexibility of the method. It is observed that, with the increase in the percentage of sodium alginate and PEG-6000 maximum amount of beads of desired size were obtained. On the other hand with the increase in HPMC percentage the distribution of particle size shifts to the higher sieve size due to increase in the internal viscosity of the medium.

3. Flow property

The flow property of the prepared formulations was checked by the method, angle of repose. Acceptable range of angle of repose is 20^0 to 40^0. All the formulations showed an angle of repose within the range.The angle of repose values are given in Table3.

4. Drug entrapment efficiency

The drug entrapment efficiency of all the formulations were in the range between 87.5% to 98.8%. Drug entrapment efficiency of microbeads increases with increase in percentage of sodium alginate, HPMC and PEG-6000. But the amount of calcium chloride has no significant effect on the drug entrapment efficiency.Results are given in table 4.

5. In-vitro dissolution studies

The formulations F1, F2, F3 containing 2%, 3% and 4% sodium alginate respectively showed a release of 93.5%,90.11% and 87.81% after 10 hours. This shows that more sustained release was observed with the increase in percentage of sodium alginate.The formulations F4 and F5 containing 4% sodium alginate + 1% HPMC and 4% sodium alginate + 2% HPMC showed a release of 76.4% and 73.6% after 12 hrs. This indicates that the release rate is further retarded due to addition and increase in percentage of HPMC.The formulations F6 and F7 containing 4% sodium alginate + 4% PEG-6000 and 4% sodium alginate + 6% PEG-6000 showed a release of 85.71% and 83.44% respectively. This shows the beads formulated with PEG-6000 prolongs the release when compared to formulations with only sodium alginate but faster release is observed when compared with formulations of HPMC.Results are given in table 5.The values of co-efficient of correlation were found to be more linear for zero order release as compared to first order. It was concluded that release of drug from formulation F1 to F7 followed zero order kinetics.Values are given in table 6. The kinetic studies were extended further and subjected to curve fitting data using PCP DISSO-V2 software to observe the mechanism of drug release. The values of co-efficient of correlation were found to be best fitted to krosmeyer-peppas model. The values of diffusion co-efficient for formulations F1 to F3 are shown to be 0.8964, 0.8825, 0.9078 respectively which indicate that the release of drug occurs by diffusion following non-fickian transport mechanism. The values of diffusion co-efficient for formulations F4 to F7 are shown to be 1.0299, 1.0039, 1.0217 and 1.1668 respectively which indicate that the release of drug occurs by case-2 transport. The % correlation coefficient Vs time are given in figures 5, 6.

6. Scanning electron microscopy

Microbeads of formulation F3 were spherical and their surface was rough giving them a sandy appearance. In case of formulation F5 the sphericity is slightly destroyed due to higher internal viscosity but uniformity is maintained. Bridging was observed, which accounts for the dense nature. The low porosity of the coating material, and larger particle size accounts for slow release of the drug.Beads of formulation F7 were almost spherical with smooth surface which may be due to the increased percentage of PEG-6000. The sizes of the beads were small compared to formulation F5.Photographs of formulations are shown in figure 1-3.

7. Stability studies

Among the seven formulations prepared F4 and F5 which showed the best release from in-vitro dissolution data were selected for stability studies.Stability study was carried out for the formulations F4 and F5 at 37 ± 1^0C and 60 ± 1^0C for a period of 45 days. The samples were analyzed for drug content at different time intervals, and it is evident that there were no changes in the content.This indicates that the formulations F4 & F5 were stable for a period of 45 days at the above mentioned temperatures.

CONCLUSION

Oral controlled release of flurbiprofen can besuccessfully achieved by ionotropic gelation techniqueusing a combination of sodium alginate-hpmc and sodium alginate-peg 6000 as polymers. Preparedmicrobeadsshown higher drugentrapment efficiency and prolonged releasecharacteristics. Flurbiprofen release from microbeadswas influenced by alginate and hpmc concentration.among the different formulations of microbeads, f-4and f-5 were estimated as best formulations because fromthese formulations drug release was observed to bein controlled manner.
